

Practicals

Practical 1: Marginal Models Continuous

- We will use the PBC dataset; this is available as the object `pb2` in the R workspace available on GitHub
- To load this workspace and make the data available execute the following steps:
 1. Open a new Rstudio session
 2. Create a new R script file (File → New File → R Script)
 3. Copy-paste and execute the following three lines

```
con <- url("https://raw.githubusercontent.com/drizopoulos/Repeated_Measurements/master/Data.RData")  
load(con)  
close(con)
```

Practical 1: Marginal Models Continuous (cont'd)

- We will need the following variables:
 - * **id**: patient id number
 - * **prothrombin**: prothrombin time in sec (the response variable of interest)
 - * **year**: follow-up times in years
 - * **drug**: the randomized treatment
 - * **sex**: the gender of the patients
 - * **age**: the age of the patients

Aim: To build an appropriate marginal model to investigate the relationships between the prothrombin time and the aforementioned variables

Practical 1: Marginal Models Continuous (cont'd)

- **Q1:** We will start by producing some descriptive plots for the prothrombin time, similar to those we have seen in Chapter 1, i.e.,
 - ▷ spaghetti plot per treatment group including the loess curve
 - ▷ spaghetti plot per sex including the loess curve

(hint: see code for Section 1.1)

What observations can you make?

Practical 1: Marginal Models Continuous (cont'd)

- **Remove outliers:** From the plots you produced in Question 1 it was evident that we have some outlying observations
 - ▷ for the rest of this practical we will exclude prothrombin times which were larger than 18 sec – to do that use the following piece of code:

```
pbc2 <- pbc2[pbc2$prothrombin < 18, ]
```

Practical 1: Marginal Models Continuous (cont'd)

- We will continue by starting our model building exercise

Remember

- ▷ we start with a full specification of the mean structure, and investigate the covariance structure
 - ▷ based on our chosen covariance structure we can make inferences for the mean structure
-
- Q2: Start by fitting a marginal model with independent error terms using `gls()` and the following specification of the mean structure (hint: see code for Section 2.4)
 - ▷ nonlinear time evolutions using natural cubic splines with 3 degrees of freedom
 - ▷ correct for `sex`, `drug` and `age`
 - ▷ interactions of the time effect with `sex` and `drug`

Practical 1: Marginal Models Continuous (cont'd)

- Q2:
 - ▷ interpret the results you obtained
 - ▷ should we simplify the model by excluding the non-significant terms?

- Q3: Continue with the same mean structure and try different covariance structures
 - ▷ first try different correlation structures, i.e., compound symmetry, continuous AR1, linear & Gaussian, and
 - ▷ then extend the above structures by assuming heteroscedastic errors, i.e., that the variance increases (or decreases) with time

(hint: see code for Section 2.9)

Practical 1: Marginal Models Continuous (cont'd)

- **Q4:** Using appropriate tools (hypothesis tests, information criteria) decide which structure is the best
 - ▷ which models are nested to which models?
- For the remainder we will use the covariance structure you have chosen in Q4
- **Q5:** Check if we can drop **all** the interaction terms
 - ▷ with an F-test
 - ▷ with a Likelihood Ratio Test

(hint: see code for Section 2.9)

Practical 1: Marginal Models Continuous (cont'd)

- **Q6:** Continue and check whether you can drop the nonlinear terms for the time effect
 - ▷ to do that fit a model that assumes a linear time trend, and
 - ▷ then do the likelihood ratio test to compare it to the model that includes the nonlinear terms
- **Q7:** Interpret the results of your final model
 - ▷ regression coefficients
 - ▷ covariance structure

Practical 1: Marginal Models Continuous (cont'd)

- **Q8:** Use an Effect Plot to depict the model with the following settings
 - ▷ **year**: in the range from 0 to 12 years of follow-up
 - ▷ **sex**: both males and females
 - ▷ **drug**: both treatment groups
 - ▷ **age**: fixed at 49 years old

(hint: see code for Section 2.4 – Effect Plot)

Practical 1: Marginal Models Continuous (cont'd)

- **Q9:** Check the assumptions of the model using scatterplots of the standardized & normalized residuals versus the fitted values,
 - ▷ overall
 - ▷ separately per sex
 - ▷ separately per treatment group

(hint: see code for Section 2.11)

What are your conclusions?

Practical 2: Mixed Models Continuous

- We will use the PBC dataset; this is available as the object `pb2` in the R workspace available on GitHub
- To load this workspace and make the data available execute the following steps:
 1. Open a new Rstudio session
 2. Create a new R script file (File → New File → R Script)
 3. Copy-paste and execute the following three lines

```
con <- url("https://raw.githubusercontent.com/drizopoulos/Repeated_Measurements/master/Data.RData")  
load(con)  
close(con)
```

Practical 2: Mixed Models Continuous (cont'd)

- We will need the following variables:
 - * **id**: patient id number
 - * **prothrombin**: prothrombin time in sec (the response variable of interest)
 - * **year**: follow-up times in years
 - * **drug**: the randomized treatment
 - * **sex**: the gender of the patients
 - * **age**: the age of the patients

Aim: To build an appropriate linear mixed effects model to investigate the relationships between the prothrombin time and the aforementioned variables

Practical 2: Mixed Models Continuous (cont'd)

- **Q1:** Compute summary statistics for the number of repeated measurements per patient
 - ▷ do we have enough information to model potential nonlinearities in the subject-specific trajectories?
- **Q2:** Examine graphically for samples of patients
(hint: see code for Section 1.1)
 - ▷ How do the individual longitudinal trajectories of the prothrombin time look like?
 - ▷ What observations can you make?

Practical 2: Mixed Models Continuous (cont'd)

- **Q3:** Start by fitting a linear mixed effects model using `lme()` with the following specification of the fixed and random effects
(hint: see code for Section 3.2)
 - ▷ *fixed effects*:
 - * linear & quadratic time evolutions, nonlinear effect of age using natural cubic splines with 3 degrees of freedom
 - * correct for `sex` and `drug`
 - * interactions of time with `sex` and `drug`, and `age` with `sex` and `drug`
 - ▷ *random effects*: random intercepts

Note: As in Practical 1, in the analysis requested above, and for the remainder of this practical exclude the prothrombin times that were above 18 sec.

Practical 2: Mixed Models Continuous (cont'd)

- **Q4:** Keeping the mean structure (i.e., the fixed effects as is), start elaborating the random-effects structure that captures the within subject correlations, i.e., consider
 - ▷ random intercepts & random slopes
 - ▷ random intercepts, linear & quadratic random slopes
 - ▷ random intercepts, linear, quadratic & cubic random slopes

For each extra random effect that you add, perform the likelihood ratio test to see if it is required to add it

- ▷ which are the null and alternative hypotheses for each of these tests?

Practical 2: Mixed Models Continuous (cont'd)

- **Q5:** Based on the model you selected Question 4, test whether you can drop all the *interaction terms* in order to simplify the model
 - ▷ first perform the omnibus test for all the interaction terms
 - ▷ if it is (highly) non-significant, you can drop them
 - ▷ if it is significant, find which group(s) are the significant ones
- **Q6:** In the same spirit as in Question 5, test whether you can drop all the *nonlinear terms* to simplify the model
 - ▷ first perform the omnibus test for all the nonlinear terms
 - ▷ if it is (highly) non-significant, you can drop them
 - ▷ if it is significant, find which group(s) are the significant ones

Practical 2: Mixed Models Continuous (cont'd)

- **Q7:** Interpret the results of your final model
 - ▷ regression coefficients
 - ▷ covariance structure
- **Q8:** Compare the marginal and subject-specific predictions from your final model, i.e.,
 - ▷ add in you data frame the marginal and subject-specific fitted values from the final model (remember to use the dataset that excludes the outliers)
 - ▷ select the following patients from the data set: 133, 36, 180, 11, 168, 116, 70, 58, 82, 104, 43, 21, 101, 210, 176, 157
 - ▷ create the plot that compares the predictions

(hint: see code for Section 3.4)

Practical 2: Mixed Models Continuous (cont'd)

- **Q9:** Use an Effect Plot to depict the model with the following settings
 - ▷ **year**: in the range from 0 to 12 years of follow-up
 - ▷ **sex**: both males and females
 - ▷ **drug**: both treatment groups
 - ▷ **age**: the median age from the original data for the respective four groups of patients (i.e., the median age of male in placebo, females in placebo, males in active treatment & females in active treatment)

(hint: see code for Section 3.2 – Effect Plot)

Practical 2: Mixed Models Continuous (cont'd)

- **Q10:** Check the assumptions of the model using scatterplots of the standardized subject-specific & standardized marginal residuals versus the fitted values,
 - ▷ overall
 - ▷ separately per sex
 - ▷ separately per treatment group

(hint: see code for Section 3.11)

What are your conclusions?

Practical 3: Marginal Models Discrete

- We will use the PBC dataset; this is available as the object `pb2` in the R workspace available on GitHub
- To load this workspace and make the data available execute the following steps:
 1. Open a new Rstudio session
 2. Create a new R script file (File → New File → R Script)
 3. Copy-paste and execute the following three lines

```
con <- url("https://raw.githubusercontent.com/drizopoulos/Repeated_Measurements/master/Data.RData")  
load(con)  
close(con)
```

Practical 3: Marginal Models Discrete (cont'd)

- We will need the following variables:
 - * **id**: patient id number
 - * **prothrombin**: prothrombin time in sec (the response variable of interest)
 - * **year**: follow-up times in years
 - * **drug**: the randomized treatment
 - * **sex**: the gender of the patients
 - * **age**: the age of the patients

Aim: To build an appropriate GEE model to investigate the relationships between a dichotomized version of the prothrombin time and the aforementioned variables

Practical 3: Marginal Models Discrete (cont'd)

- **Q1:** A normal prothrombin time is between 11 and 13 sec
 - ▷ create a dichotomous variable, with '0' denoting a normal prothrombin time, and '1' an abnormal one
- **Q2:** Examine graphically the probability of abnormal prothrombin time
(hint: see code for Section 1.1)
 - ▷ separately per treatment including the loess curve
 - ▷ separately per sex including the loess curve
 - ▷ separately for each age category [25, 43], [43, 50], [50, 55] and [55, 80] including the loess curve
 - ▷ what observations can you make?

Practical 3: Marginal Models Discrete (cont'd)

- **Q3:** The researchers in this study made the following conjectures
 - ▷ the log odds of abnormal prothrombin time may evolve nonlinear during follow-up;
 - ▷ in addition, it is plausible that the log odds evolutions in time are different between males and females, and between placebo and treated patients;
 - ▷ furthermore, age is an important risk factor, and the effect of age may be modified by sex

Translate the above conjectures into a suitable GEE model for the log odds of abnormal prothrombin time

- ▷ use the exchangeable working correlation matrix, and
- ▷ for the nonlinear terms use natural cubic splines with 2 degrees of freedom

(hint: see code for Section 4.3)

Practical 3: Marginal Models Discrete (cont'd)

- **Q4:** Re-fit the model you fitted in Question 3 by assuming
 - ▷ an independence working correlation matrix, and
 - ▷ an AR1 working correlation matrix
- ▷ Compare the estimated coefficients and the corresponding naive and sandwich standard errors using a coefficients' plot
(hint: see code for Section 4.5)
- ▷ Which working correlation matrix do you choose and why?

Practical 3: Marginal Models Discrete (cont'd)

- **Q5:** The researchers in the study want to see if the model can be simplified by dropping the *interaction terms*
 - ▷ first perform the omnibus test for all the interaction terms
 - ▷ if it is (highly) non-significant, you can drop them
 - ▷ if it is significant, find which group(s) are the significant ones
- **Q6:** Do the same for the *nonlinear terms*, i.e.,
 - ▷ first perform the omnibus test for all the nonlinear terms
 - ▷ if it is (highly) non-significant, you can drop them
 - ▷ if it is significant, find which group(s) are the significant ones

Practical 3: Marginal Models Discrete (cont'd)

- Q7: Interpret the results of your final model
- Q8: Use an Effect Plot to depict the model with the following settings
 - ▷ **year**: in the range from 0 to 12 years of follow-up
 - ▷ **sex**: both males and females
 - ▷ **drug**: both treatment groups
 - ▷ **age**: 49 years old

(hint: see code for Section 4.3 – Effect Plot)

Do the plot in both the log odds and probability scales

Practical 3: Marginal Models Discrete (cont'd)

- **Q9:** From the effect plot we observe that the trajectories of the log odds for males and females in the D-penicillamine group are nonlinear (more so for the females)
 - ▷ test in males and females separately
 - ▷ with age 49 years old
 - ▷ whether there are differences in the log odds of abnormal prothrombin time
 - ▷ at the follow-up years 2, 6, 8 and 10
 - ▷ in other words, perform all the pairwise comparisons for the aforementioned follow-up times
 - ▷ should you adjust for multiple comparisons?

(hint: see code for Section 4.6 – complex effects)

Practical 4: Mixed Models Discrete
